SUVIDHA ONE

Rust Backend

Complete Developer Documentation

Architected for 1,000,000+ Users Per Minute

DOCUMENT OVERVIEW	
Team	The_Dark_Knight	ID: 21
Project	SUVIDHA ONE — Unified Citizen Service Kiosk
Runtime	Rust (Axum + Tokio) — async, zero-cost abstractions
Target Scale	1,000,000+ authenticated requests per minute
Database	PostgreSQL 16 + Redis 7 + MinIO (S3)
Auth	JWT (RS256) + Aadhaar OTP + QR Session
Version	1.0	February 2026

Table of Contents

1. Introduction to the Backend Architecture *3*
2. Authentication — OTP, Aadhaar & Session Design *5*
3. JSON Web Tokens (JWT) — RS256 Implementation *8*
4. Authorization — RBAC & Middleware *10*
5. Web & API Security Best Practices *12*
6. Business Logic Layer (BLL) *15*
7. Caching Strategies — Redis + CDN *17*
8. Error Handling & Error Codes *19*
9. OpenAPI / OpenAI Standards & API Design *21*
10. Webhooks — Design & Delivery *23*
11. Logging, Monitoring & Observability *25*
12. Testing & Code Quality *27*
13. Configuration Management *29*
14. Database Interactions & CRUD Operations *31*
15. Serialization & Deserialization (Serde) *34*
16. Appendix — Dependencies, Env Vars & Ports *36*

SECTION 1 — Introduction to the Backend Architecture

1. Introduction to the Backend Architecture

SUVIDHA ONE's Rust backend is purpose-built to serve over one million authenticated citizen requests per minute across a nationwide fleet of public kiosks. Every architectural choice — from the async runtime to the data access layer — is motivated by three non-negotiable goals: safety, throughput, and auditability.

1.1 Why Rust?

CRITERION	RUST ADVANTAGE	IMPACT AT SCALE
Memory Safety	Ownership model eliminates data races, use-after-free, buffer overflows — at compile time	Zero security-class memory bugs in production
Performance	Zero-cost abstractions; performance matches C/C++ without GC pauses	Consistent sub-10ms p99 latency at 1M req/min
Concurrency	Tokio async runtime — millions of lightweight tasks on a thread pool	Handles 50k+ concurrent kiosk connections per node
Type Safety	Exhaustive pattern matching; Result<T,E> forces error handling	Reduces runtime panics to near zero in production
Correctness	Compiler as a code reviewer; impossible states are unrepresentable	Complex payment state machine enforced at compile time
Ecosystem	Axum (web), SQLx (DB), Serde (JSON), Tokio (async), Tower (middleware)	Best-in-class crates for every backend concern

1.2 Five-Layer Architecture

The backend maps directly onto the five-layer system architecture:

LAYER	COMPONENT	RUST CRATE / TECH	RESPONSIBILITY
1 — Edge	NGINX reverse proxy	NGINX + Kong	TLS termination, rate-limit, DDoS protection
2 — Gateway	Axum API Gateway router	axum 0.7, tower	Auth middleware, request routing, CORS
3 — Services	8 Axum microservices	axum, tokio, tonic (gRPC)	Business logic per domain (auth, payment, etc.)

4 — Data	PostgreSQL / Redis / MinIO	sqlx, deadpool-redis, aws-sdk-s3	Persistence, caching, document storage
5 — Integrations	UIDAI, NPCI, DigiLocker	reqwest, hyper	Government API adapters with circuit breakers

1.3 Microservice Topology

SERVICE	PORT	DESCRIPTION
auth-service	3001	OTP, Aadhaar, QR auth; JWT issuance & refresh
payment-service	3002	UPI, Card, BBPS payment orchestration
utility-service	3003	Electricity, Water, Gas, Municipal bill fetch & actions
grievance-service	3004	Complaint filing, tracking, escalation engine
document-service	3005	DigiLocker integration, certificate apply/download
notification-service	3006	SMS, WhatsApp, push notifications (async queue)
session-service	3007	Kiosk session state, idle timeout management
kiosk-service	3008	Kiosk registration, heartbeat, OTA config delivery

SECTION 2 — Authentication: OTP, Aadhaar & Session Design

2. Authentication — OTP, Aadhaar & Session Design

Authentication is the most security-critical layer. SUVIDHA ONE supports three authentication flows — Mobile OTP, Aadhaar Biometric (via UIDAI AUA), and QR Code session transfer. Each flow produces an identical JWT + Refresh Token pair so downstream services have a uniform interface.

2.1 Authentication Flow Overview

FLOW	STEPS	SECURITY PROPERTIES
Mobile OTP	1. POST /auth/otp/send → generate 6-digit TOTP, store in Redis (TTL 300s) 2. POST /auth/otp/verify → compare hash, rate-limit 3 attempts 3. Upsert user row → generate JWT + refresh token	OTP hashed (HMAC-SHA256) in Redis; never stored plain; brute-force blocked at 3 attempts/IP/5min
Aadhaar Biometric	1. POST /auth/aadhaar/init → get session token from UIDAI AUA API 2. Kiosk scans fingerprint → POST /auth/aadhaar/verify → UIDAI validates 3. Receive tokenized UID (VID) → upsert user → generate JWT	VID used — raw Aadhaar number never touches our DB; UIDAI AUA certified; mTLS to UIDAI endpoint
QR Code	1. Citizen scans personal QR from DigiLocker/Aadhaar app 2. POST /auth/qr/scan → decode signed payload, verify signature 3. Extract user identity → generate JWT	QR payload signed by DigiLocker; expiry embedded; replay protected via nonce in Redis

2.2 OTP Service Implementation

OTP Generation & Storage

```
// src/services/otp.rs
use hmac::{Hmac, Mac};
use sha2::Sha256;
use redis::AsyncCommands;

const OTP_TTL_SECS: usize = 300;   // 5 minutes
const OTP_MAX_ATTEMPTS: u8 = 3;

pub async fn send_otp(
    mobile: &str,
    redis: &mut redis::aio::Connection,
    sms_client: &SmsClient,
) -> Result<(), AppError> {
    // 1. Rate-limit check: max 3 OTPs per mobile per 10 min
    let rate_key = format!("otp:rate:{}", mobile);
    let count: u8 = redis.incr(&rate_key, 1).await?;
```

```
    if count == 1 { redis.expire(&rate_key, 600).await?; }
    if count > 3 { return Err(AppError::RateLimitExceeded); }

    // 2. Generate cryptographically random 6-digit OTP
    let otp: u32 = rand::thread_rng().gen_range(100_000..=999_999);

    // 3. Store HMAC-SHA256 hash of OTP (never plaintext)
    let secret = std::env::var("OTP_HMAC_SECRET")?;
    let mut mac = Hmac::<Sha256>::new_from_slice(secret.as_bytes())
        .map_err(|_| AppError::Internal("HMAC init failed".into()))?;
    mac.update(otp.to_string().as_bytes());
    let otp_hash = hex::encode(mac.finalize().into_bytes());

    // 4. Store hash + attempt counter in Redis
    let key = format!("otp:hash:{}", mobile);
    redis.set_ex(&key, &otp_hash, OTP_TTL_SECS).await?;
    let attempt_key = format!("otp:attempts:{}", mobile);
    redis.set_ex(&attempt_key, 0u8, OTP_TTL_SECS).await?;

    // 5. Send OTP via SMS (actual digits sent to user, hash kept)
    sms_client.send(mobile, &format!("Your SUVIDHA ONE OTP: {}", otp)).await?;
    Ok(())
}
```

OTP Verification

```
pub async fn verify_otp(
    mobile: &str,
    submitted_otp: &str,
    redis: &mut redis::aio::Connection,
) -> Result<(), AppError> {
    // 1. Check attempt count
    let attempt_key = format!("otp:attempts:{}", mobile);
    let attempts: u8 = redis.get(&attempt_key).await.unwrap_or(0);
    if attempts >= OTP_MAX_ATTEMPTS {
        return Err(AppError::Auth(AuthError::OtpMaxAttemptsExceeded));
    }
    redis.incr::<_, u8>(&attempt_key, 1).await?;

    // 2. Recompute hash of submitted OTP
    let secret = std::env::var("OTP_HMAC_SECRET")?;
    let mut mac = Hmac::<Sha256>::new_from_slice(secret.as_bytes())
        .map_err(|_| AppError::Internal("HMAC init".into()))?;
    mac.update(submitted_otp.as_bytes());
    let submitted_hash = hex::encode(mac.finalize().into_bytes());

    // 3. Compare against stored hash (constant-time)
    let stored_key = format!("otp:hash:{}", mobile);
    let stored_hash: Option<String> = redis.get(&stored_key).await?;
    match stored_hash {
        Some(h) if constant_time_eq(h.as_bytes(), submitted_hash.as_bytes()) =>
{
            // 4. Delete OTP keys on success
            redis.del(&[&stored_key, &attempt_key]).await?;
            Ok(())
        }
        Some(_) => Err(AppError::Auth(AuthError::InvalidOtp)),
        None    => Err(AppError::Auth(AuthError::OtpExpired)),
    }
}
```

2.3 Session Management

Sessions are stored server-side in Redis. The JWT is stateless but every request is also checked against the Redis session store. This enables instant logout — deleting the Redis key invalidates the token even if its JWT expiry has not passed.

```
// Session struct stored in Redis as JSON
#[derive(Debug, Serialize, Deserialize)]
pub struct Session {
    pub session_id:   Uuid,
    pub user_id:      Uuid,
    pub kiosk_id:     String,
    pub auth_method:  AuthMethod,  // Otp | Aadhaar | Qr
    pub created_at:   DateTime<Utc>,
    pub last_active:  DateTime<Utc>,
    pub idle_timeout: u64,   // seconds, default 180 (3 min)
    pub hard_timeout: u64,   // seconds, default 900 (15 min)
}

pub async fn create_session(
    user_id: Uuid,
    kiosk_id: &str,
    auth_method: AuthMethod,
    redis: &mut redis::aio::Connection,
) -> Result<Session, AppError> {
    let session = Session {
        session_id:   Uuid::new_v4(),
        user_id,
        kiosk_id:     kiosk_id.to_owned(),
        auth_method,
        created_at:   Utc::now(),
        last_active:  Utc::now(),
        idle_timeout: 180,
        hard_timeout: 900,
    };
    let key = format!("session:{}", session.session_id);
    let json = serde_json::to_string(&session)?;
    redis.set_ex(&key, json, 900usize).await?;  // Hard timeout TTL
    Ok(session)
}
```

SECTION 3 — JSON Web Tokens (JWT): RS256 Implementation

3. JSON Web Tokens — RS256 Implementation

SUVIDHA ONE uses asymmetric RS256 JWTs. The auth-service holds the RSA private key for signing; all other microservices verify tokens using only the public key. This means a compromised downstream service cannot forge tokens.

3.1 JWT Claims Structure

```
/// Access token claims (expires in 15 minutes)
#[derive(Debug, Serialize, Deserialize)]
pub struct AccessClaims {
    pub sub:    Uuid,          // user_id
    pub jti:    Uuid,          // unique token ID (for blacklist check)
    pub iat:    i64,           // issued at (Unix timestamp)
    pub exp:    i64,           // expiry (iat + 900 seconds)
    pub iss:    String,        // "suvidha-one-auth"
    pub aud:    Vec<String>,   // ["suvidha-one-api"]
    pub kiosk:  String,        // kiosk_id — request must originate here
    pub roles:  Vec<Role>,     // [Citizen, KioskAdmin, SystemAdmin]
    pub lang:   String,        // preferred language (for BFF responses)
}

/// Refresh token claims (expires in 7 days)
#[derive(Debug, Serialize, Deserialize)]
pub struct RefreshClaims {
    pub sub:    Uuid,
    pub jti:    Uuid,
    pub iat:    i64,
    pub exp:    i64,           // iat + 604800 seconds (7 days)
    pub family: Uuid,          // token family for rotation detection
}
```

3.2 Token Issuance

```
use jsonwebtoken::{encode, Algorithm, EncodingKey, Header};

pub struct JwtService {
    private_key: EncodingKey,  // RSA-2048 PEM loaded at startup
    public_key:  DecodingKey,
}

impl JwtService {
    pub fn new(private_pem: &[u8], public_pem: &[u8]) -> Result<Self, AppError>
{
        Ok(Self {
            private_key: EncodingKey::from_rsa_pem(private_pem)?,
            public_key:  DecodingKey::from_rsa_pem(public_pem)?,
        })
    }
```

```
    pub fn issue_access_token(&self, claims: &AccessClaims) -> Result<String,
AppError> {
        let header = Header::new(Algorithm::RS256);
        encode(&header, claims, &self.private_key)
            .map_err(|e| AppError::JwtEncoding(e.to_string()))
    }

    pub fn verify_access_token(&self, token: &str) -> Result<AccessClaims,
AppError> {
        let mut validation = Validation::new(Algorithm::RS256);
        validation.set_issuer(&["suvidha-one-auth"]);
        validation.set_audience(&["suvidha-one-api"]);
        decode::<AccessClaims>(token, &self.public_key, &validation)
            .map(|td| td.claims)
            .map_err(|e| match e.kind() {
                ErrorKind::ExpiredSignature =>
AppError::Auth(AuthError::TokenExpired),
                ErrorKind::InvalidAudience  =>
AppError::Auth(AuthError::InvalidToken),
                _                           =>
AppError::Auth(AuthError::InvalidToken),
            })
    }
}
```

3.3 Refresh Token Rotation

> *Token families prevent refresh token reuse attacks. If a compromised token is used after rotation, the family is invalidated, logging out all sessions for that user.*

```
pub async fn refresh_tokens(
    refresh_token: &str,
    jwt_svc: &JwtService,
    redis: &mut redis::aio::Connection,
    db: &PgPool,
) -> Result<(String, String), AppError> {
    // 1. Verify refresh token signature & expiry
    let claims = jwt_svc.verify_refresh_token(refresh_token)?;

    // 2. Check token is not already used (rotation detection)
    let used_key = format!("rt:used:{}", claims.jti);
    if redis.exists(&used_key).await? {
        // Replay attack detected — invalidate entire family
        let family_key = format!("rt:family:{}", claims.family);
        redis.del(&family_key).await?;
        return Err(AppError::Auth(AuthError::RefreshTokenReplay));
    }

    // 3. Mark old token as used
    redis.set_ex(&used_key, 1u8, 604_800usize).await?;

    // 4. Issue new access + refresh token pair
    let user = fetch_user_by_id(db, claims.sub).await?;
    let new_access  = jwt_svc.issue_access_token(&build_access_claims(&user))?;
    let new_refresh = jwt_svc.issue_refresh_token(&build_refresh_claims(&user,
claims.family))?;
    Ok((new_access, new_refresh))
}
```

SECTION 4 — Authorization: RBAC & Tower Middleware

4. Authorization — RBAC & Tower Middleware

Authorization is enforced via Tower middleware layers in Axum. Roles are embedded in the JWT claims and checked before any handler runs. This means no handler ever receives an unauthorized request — the middleware layer short-circuits with a 403 before the BLL is invoked.

4.1 Role Definitions

ROLE	PERMISSIONS
Citizen	Read own profile, pay bills, file complaints, apply for certificates, view own history
KioskAdmin	All Citizen permissions + register kiosk, view kiosk health, push OTA config
DeptOfficer	All Citizen + view/update complaints in own department, verify documents
SystemAdmin	All permissions + manage users, view all audit logs, manage kiosk fleet
ServiceAccount	Machine-to-machine only — notification delivery, heartbeat, webhook receipt

4.2 JWT Middleware Implementation

```
use axum::{extract::State, http::{Request, StatusCode}, middleware::Next,
response::Response};

/// Tower middleware — validates JWT and injects claims into request extensions
pub async fn jwt_auth_middleware<B>(
    State(jwt_svc): State<Arc<JwtService>>,
    State(redis):   State<Arc<RedisPool>>,
    mut req: Request<B>,
    next:    Next<B>,
) -> Result<Response, AppError> {
    // 1. Extract Bearer token from Authorization header
    let token = req
        .headers()
        .get("Authorization")
        .and_then(|v| v.to_str().ok())
        .and_then(|v| v.strip_prefix("Bearer "))
        .ok_or(AppError::Auth(AuthError::MissingToken))?;

    // 2. Verify JWT signature, expiry, issuer, audience
    let claims = jwt_svc.verify_access_token(token)?;

    // 3. Check Redis session store (enables instant logout)
    let session_key = format!("session:{}", claims.jti);
    let mut conn = redis.get().await?;
    if !conn.exists::<_, bool>(&session_key).await? {
        return Err(AppError::Auth(AuthError::SessionInvalidated));
    }
```

```
    // 4. Refresh idle timer in session store
    conn.expire(&session_key, 180i64).await?;

    // 5. Inject verified claims for handlers to extract
    req.extensions_mut().insert(claims);
    Ok(next.run(req).await)
}

/// Role-check extractor — usage: Extension<RequireRole<Citizen>>
pub async fn require_role<B, R: RoleCheck>(
    Extension(claims): Extension<AccessClaims>,
    req: Request<B>,
    next: Next<B>,
) -> Result<Response, AppError> {
    if !R::is_allowed(&claims.roles) {
        return Err(AppError::Forbidden("Insufficient role".into()));
    }
    Ok(next.run(req).await)
}
```

4.3 Router Configuration with Middleware Layers

```
use axum::{middleware, Router};

pub fn build_router(state: AppState) -> Router {
    let public_routes = Router::new()
        .route("/auth/otp/send",     post(handlers::otp::send))
        .route("/auth/otp/verify",   post(handlers::otp::verify))
        .route("/auth/aadhaar/init",post(handlers::aadhaar::init))
        .route("/services",          get(handlers::services::list));

    let citizen_routes = Router::new()
        .route("/user/profile",      get(handlers::user::profile))
        .route("/bills/pay",         post(handlers::bills::pay))
        .route("/grievance/file",    post(handlers::grievance::file))
        .layer(middleware::from_fn_with_state(
            state.clone(),
            jwt_auth_middleware,    // JWT + session check
        ))
        .layer(middleware::from_fn(require_role::<Citizen>));

    let admin_routes = Router::new()
        .route("/kiosk/register",    post(handlers::kiosk::register))
        .layer(middleware::from_fn_with_state(state.clone(),
jwt_auth_middleware))
        .layer(middleware::from_fn(require_role::<SystemAdmin>));

    Router::new()
        .merge(public_routes)
        .nest("/api/v1", citizen_routes)
        .nest("/api/v1/admin", admin_routes)
        .with_state(state)
}
```

SECTION 5 — Web & API Security Best Practices

5. Web & API Security Best Practices

5.1 Security Headers Middleware

```
use axum::http::{header, HeaderValue};
use tower_http::set_header::SetResponseHeaderLayer;

pub fn security_headers() -> impl tower::Layer<axum::routing::Router> {
    tower::ServiceBuilder::new()
        // Prevent clickjacking
        .layer(SetResponseHeaderLayer::overriding(
            header::X_FRAME_OPTIONS,
            HeaderValue::from_static("DENY"),
        ))
        // Disable MIME sniffing
        .layer(SetResponseHeaderLayer::overriding(
            header::X_CONTENT_TYPE_OPTIONS,
            HeaderValue::from_static("nosniff"),
        ))
        // Strict HTTPS (1 year)
        .layer(SetResponseHeaderLayer::overriding(
            header::STRICT_TRANSPORT_SECURITY,
            HeaderValue::from_static("max-age=31536000; includeSubDomains;
preload"),
        ))
        // Content Security Policy
        .layer(SetResponseHeaderLayer::overriding(
            header::CONTENT_SECURITY_POLICY,
            HeaderValue::from_static(
                "default-src 'self'; script-src 'self'; style-src 'self'
fonts.googleapis.com"
            ),
        ))
        // Referrer Policy
        .layer(SetResponseHeaderLayer::overriding(
            header::REFERRER_POLICY,
            HeaderValue::from_static("strict-origin-when-cross-origin"),
        ))
}
```

5.2 Input Validation

> *All input validation happens at the deserialization boundary using the validator crate. Invalid requests are rejected before they reach any handler or BLL code.*

```
use validator::Validate;

#[derive(Debug, Deserialize, Validate)]
pub struct SendOtpRequest {
    #[validate(length(min = 10, max = 10), regex(path = "MOBILE_REGEX"))]
```

```
    pub mobile: String,
}

#[derive(Debug, Deserialize, Validate)]
pub struct PayBillRequest {
    #[validate(length(min = 1))]
    pub bill_ids: Vec<Uuid>,
    #[validate(range(min = 1.0, max = 100_000.0))]
    pub amount:   f64,
    pub method:   PaymentMethod,   // enum — no raw strings
}

/// Generic validated extractor for all request bodies
pub struct Validated<T>(pub T);

#[async_trait]
impl<S, T> FromRequest<S> for Validated<T>
where
    T: DeserializeOwned + Validate,
    S: Send + Sync,
{
    type Rejection = AppError;

    async fn from_request(req: Request, state: &S) -> Result<Self,
Self::Rejection> {
        let Json(value) = Json::<T>::from_request(req, state).await
            .map_err(|e| AppError::Validation(e.to_string()))?;
        value.validate()
            .map_err(|e| AppError::Validation(e.to_string()))?;
        Ok(Validated(value))
    }
}
```

5.3 Rate Limiting Strategy

TIER	LIMIT	WINDOW	ENFORCEMENT
Global (per IP)	1,000 requests	1 minute	NGINX + Kong
Auth endpoints	5 attempts	1 minute	Redis sliding window
OTP send	3 OTPs per mobile	10 min	Redis counter
Payment init	10 payments per session	15 min	Redis + DB check
Admin endpoints	100 requests per token	1 minute	Tower middleware

```
// Redis sliding window rate limiter
pub async fn check_rate_limit(
    redis: &mut redis::aio::Connection,
    key: &str,
    max: u64,
    window_secs: u64,
) -> Result<(), AppError> {
    let now = SystemTime::now().duration_since(UNIX_EPOCH)?.as_millis() as u64;
    let window_start = now - (window_secs * 1000);
```

```
    // Use Redis sorted set for sliding window
    let _: () = redis
        .zrembyscore(key, "-inf", window_start as f64)
        .await?;
    let count: u64 = redis.zcard(key).await?;
    if count >= max {
        return Err(AppError::RateLimitExceeded);
    }
    let _: () = redis.zadd(key, now as f64, now).await?;
    redis.expire(key, window_secs as i64).await?;
    Ok(())
}
```

5.4 SQL Injection Prevention

> *SUVIDHA ONE uses SQLx exclusively with compile-time verified parameterized queries. String interpolation into SQL is a compile error — not a runtime risk.*

```
// ✅ CORRECT — compile-time checked, parameterized
let user = sqlx::query_as!(User,
    "SELECT * FROM users WHERE mobile_hash = $1 AND is_active = true",
    mobile_hash
)
.fetch_optional(&db)
.await?;

// ❌ IMPOSSIBLE with SQLx — the compiler prevents this
// let query = format!("SELECT * FROM users WHERE mobile = '{}'", mobile);
```

SECTION 6 — Business Logic Layer (BLL)

6. Business Logic Layer (BLL)

The BLL is the core of each microservice. It contains pure Rust logic — no HTTP, no DB, no Redis. This separation makes the BLL independently unit-testable and means the same logic can be called from an HTTP handler, a gRPC handler, or a background job.

6.1 BLL Architecture Principles

- Pure functions — BLL functions take typed inputs and return typed outputs. Side effects (DB, cache, notifications) are injected as trait objects.
- Repository pattern — The BLL depends on repository traits, not concrete DB implementations. This enables mock repositories in tests.
- Domain errors — All BLL errors are typed via thiserror, never raw strings.
- Idempotency — Payment and complaint operations are idempotency-keyed to prevent double submission.
- Transaction boundaries — DB transactions are managed at the BLL level, ensuring atomicity across multiple tables.

6.2 Repository Trait Pattern

```
// Trait definition (in shared crate)
#[async_trait]
pub trait UserRepository: Send + Sync {
    async fn find_by_id(&self, id: Uuid) -> Result<Option<User>, DbError>;
    async fn find_by_mobile_hash(&self, hash: &str) -> Result<Option<User>,
DbError>;
    async fn upsert(&self, user: &UpsertUser) -> Result<User, DbError>;
    async fn update_preferences(&self, id: Uuid, prefs: &Preferences) ->
Result<(), DbError>;
}

// Concrete implementation (uses SQLx)
pub struct PgUserRepository { pool: PgPool }

#[async_trait]
impl UserRepository for PgUserRepository {
    async fn find_by_id(&self, id: Uuid) -> Result<Option<User>, DbError> {
        Ok(sqlx::query_as!(User, "SELECT * FROM users WHERE user_id = $1", id)
            .fetch_optional(&self.pool).await?)
    }
    // ... other implementations
}
```

6.3 Payment BLL — Idempotency Example

```
pub struct PaymentService {
    payment_repo:  Arc<dyn PaymentRepository>,
    bill_repo:     Arc<dyn BillRepository>,
```

```
    npci_client:   Arc<dyn NpciGateway>,
    notification:  Arc<dyn NotificationService>,
}

impl PaymentService {
    /// Pay one or more bills atomically.
    /// idempotency_key prevents duplicate payments on network retry.
    pub async fn pay_bills(
        &self,
        user_id: Uuid,
        bill_ids: &[Uuid],
        method: PaymentMethod,
        idempotency_key: Uuid,
    ) -> Result<PaymentReceipt, PaymentError> {
        // 1. Check idempotency — return existing receipt if key already used
        if let Some(existing) =
self.payment_repo.find_by_idempotency_key(idempotency_key).await? {
            return Ok(existing.into_receipt());
        }

        // 2. Fetch and validate bills
        let bills = self.bill_repo.fetch_many(bill_ids).await?;
        for bill in &bills {
            if bill.user_id != user_id { return
Err(PaymentError::Unauthorized); }
            if bill.status == BillStatus::Paid { return
Err(PaymentError::AlreadyPaid); }
        }
        let total = bills.iter().map(|b| b.amount).sum::<Decimal>();

        // 3. Initiate payment with NPCI/BBPS (external call with retry)
        let tx_ref = self.npci_client.initiate(total, method).await?;

        // 4. Persist payment record (atomic transaction)
        let receipt = self.payment_repo.create_with_idempotency(
            idempotency_key, user_id, &bills, tx_ref, total
        ).await?;

        // 5. Fire async notifications (non-blocking)
        let receipt_clone = receipt.clone();
        tokio::spawn(async move {
            self.notification.send_receipt(&receipt_clone).await
                .unwrap_or_else(|e| tracing::error!("Notification failed: {}",
e));
        });

        Ok(receipt)
    }
}
```

SECTION 7 — Caching Strategies: Redis + CDN

7. Caching Strategies — Redis + CDN

7.1 Cache Taxonomy

CACHE LAYER	TECHNOLOGY	TTL	WHAT IS CACHED
OTP codes	Redis	300 s	HMAC hash of OTP; attempt counter
Active sessions	Redis	900 s	Full Session struct as JSON
Rate limits	Redis	60–600 s	Sorted-set sliding windows per key
Bill data	Redis	1800 s	BBPS bill fetch response per consumer_id
User profile	Redis	300 s	User struct after first DB fetch in session
Service list	Redis	3600 s	Full services JSON (rarely changes)
Kiosk config	Redis	1800 s	Per-kiosk config JSON
Static assets	CloudFront	86400 s	JS, CSS, icons, fonts
Offline cache	IndexedDB	Persistent	Service definitions for offline kiosk use

7.2 Redis Connection Pool

```
use deadpool_redis::{Config, Pool, Runtime};

pub fn create_redis_pool(redis_url: &str) -> Result<Pool, AppError> {
    let cfg = Config::from_url(redis_url);
    cfg.create_pool(Some(Runtime::Tokio1))
        .map_err(|e| AppError::Infrastructure(e.to_string()))
}

/// Generic cache helper with serialization
pub async fn cache_get_or_fetch<T, F, Fut>(
    redis: &Pool,
    key: &str,
    ttl: u64,
    fetch: F,
) -> Result<T, AppError>
where
    T: Serialize + DeserializeOwned,
    F: FnOnce() -> Fut,
    Fut: Future<Output = Result<T, AppError>>,
{
    let mut conn = redis.get().await?;
    // Try cache first
```

```
    if let Ok(cached) = conn.get::<_, String>(key).await {
        if let Ok(val) = serde_json::from_str::<T>(&cached) {
            return Ok(val);
        }
    }
    // Cache miss — fetch from source
    let val = fetch().await?;
    let json = serde_json::to_string(&val)?;
    conn.set_ex(key, json, ttl as usize).await?;
    Ok(val)
}
```

7.3 Cache Invalidation

```
// Invalidate user profile cache on profile update
pub async fn update_user_profile(
    db: &PgPool,
    redis: &Pool,
    user_id: Uuid,
    update: &UpdateProfile,
) -> Result<User, AppError> {
    // 1. Update in DB
    let updated = sqlx::query_as!(User, /* ... */ ).fetch_one(db).await?;

    // 2. Invalidate cache — next request will re-fetch from DB
    let cache_key = format!("user:profile:{}", user_id);
    let mut conn = redis.get().await?;
    conn.del(&cache_key).await?;

    Ok(updated)
}
```

SECTION 8 — Error Handling & Error Codes

8. Error Handling & Error Codes

Rust's type system enforces that every error path is explicitly handled. SUVIDHA ONE uses a hierarchical AppError enum that implements Axum's IntoResponse trait, converting domain errors into structured JSON HTTP responses with correct status codes and application-level error codes.

8.1 AppError Enum

```
use thiserror::Error;
use axum::http::StatusCode;
use axum::response::{IntoResponse, Json, Response};

#[derive(Debug, Error)]
pub enum AppError {
    #[error("Authentication error: {0}")]
    Auth(#[from] AuthError),

    #[error("Payment error: {0}")]
    Payment(#[from] PaymentError),

    #[error("Validation error: {0}")]
    Validation(String),

    #[error("Not found: {0}")]
    NotFound(String),

    #[error("Forbidden: {0}")]
    Forbidden(String),

    #[error("Rate limit exceeded")]
    RateLimitExceeded,

    #[error("External API error: {0}")]
    ExternalApi(String),

    #[error("Database error: {0}")]
    Database(#[from] sqlx::Error),

    #[error("Cache error: {0}")]
    Cache(String),

    #[error("Internal error: {0}")]
    Internal(String),
}
```

8.2 IntoResponse Implementation

```
#[derive(Serialize)]
struct ErrorResponse {
    error_code: u32,
```

```
    message:    String,
    request_id: Uuid,   // from request extensions for traceability
}

impl IntoResponse for AppError {
    fn into_response(self) -> Response {
        let (status, code, message) = match &self {
            AppError::Auth(AuthError::MissingToken)         =>
(StatusCode::UNAUTHORIZED,  1001, self.to_string()),
            AppError::Auth(AuthError::TokenExpired)         =>
(StatusCode::UNAUTHORIZED,  1002, self.to_string()),
            AppError::Auth(AuthError::InvalidOtp)           =>
(StatusCode::UNAUTHORIZED,  1003, self.to_string()),
            AppError::Auth(AuthError::OtpExpired)           =>
(StatusCode::UNAUTHORIZED,  1004, self.to_string()),
            AppError::Auth(AuthError::SessionInvalidated)   =>
(StatusCode::UNAUTHORIZED,  1005, self.to_string()),
            AppError::Auth(AuthError::RefreshTokenReplay)   =>
(StatusCode::UNAUTHORIZED,  1006, self.to_string()),
            AppError::Payment(PaymentError::AlreadyPaid)    =>
(StatusCode::CONFLICT,      2001, self.to_string()),
            AppError::Payment(PaymentError::Unauthorized)   =>
(StatusCode::FORBIDDEN,     2002, self.to_string()),
            AppError::Payment(PaymentError::GatewayError)   =>
(StatusCode::BAD_GATEWAY,   2003, self.to_string()),
            AppError::Validation(_)                         =>
(StatusCode::BAD_REQUEST,    9001, self.to_string()),
            AppError::NotFound(_)                           =>
(StatusCode::NOT_FOUND,      9002, self.to_string()),
            AppError::Forbidden(_)                          =>
(StatusCode::FORBIDDEN,      9003, self.to_string()),
            AppError::RateLimitExceeded                     =>
(StatusCode::TOO_MANY_REQUESTS, 9004, "Rate limit exceeded. Please
wait.".into()),
            AppError::ExternalApi(_)                        =>
(StatusCode::BAD_GATEWAY,    9005, "External service unavailable.".into()),
            AppError::Database(_) | AppError::Internal(_)   => {
                // Never leak internal error details to client
                tracing::error!("Internal error: {:?}", self);
                (StatusCode::INTERNAL_SERVER_ERROR, 9999, "An internal error
occurred.".into())
            }
            _ => (StatusCode::INTERNAL_SERVER_ERROR, 9999, "Unexpected
error.".into()),
        };
        (status, Json(ErrorResponse { error_code: code, message, request_id:
Uuid::new_v4() }))
            .into_response()
    }
}
```

8.3 Error Code Reference

CODE RANGE	DOMAIN	EXAMPLE CODES	HTTP STATUS
1000–1099	Authentication	1001 Missing token, 1002 Expired, 1003 Bad OTP	401, 403
2000–2099	Payment	2001 Already paid, 2002 Unauthorized, 2003 Gateway	402, 403, 502

3000–3099	Bills/Utility	3001 Bill not found, 3002 BBPS error	404, 502
4000–4099	Grievance	4001 Not found, 4002 Already closed	404, 409
5000–5099	Certificates	5001 Not eligible, 5002 DigiLocker error	403, 502
9000–9099	System	9001 Validation, 9002 Not found, 9999 Internal	400, 404, 500

SECTION 9 — OpenAPI Standards & API Design

9. OpenAPI Standards & API Design

9.1 OpenAPI 3.1 Specification

Every SUVIDHA ONE API endpoint is documented via OpenAPI 3.1. The spec is auto-generated from code using utoipa (Rust OpenAPI annotations). The Swagger UI is served at /docs in non-production environments.

```
use utoipa::{OpenApi, ToSchema};

#[derive(OpenApi)]
#[openapi(
    paths(
        crate::routes::otp::send_otp,
        crate::routes::otp::verify_otp,
        crate::routes::bills::pay_bills,
    ),
    components(schemas(SendOtpRequest, VerifyOtpRequest, PayBillRequest,
ApiErrorResponse)),
    info(
        title = "SUVIDHA ONE API",
        version = "1.0.0",
        description = "Unified Citizen Service Kiosk Backend",
        contact(name = "Team The_Dark_Knight", email =
"team@suvidhaone.gov.in"),
    ),
    tags(
        (name = "auth",      description = "Authentication endpoints"),
        (name = "bills",     description = "Bill fetch and payment"),
        (name = "grievance", description = "Complaint management"),
    ),
    security(("", &[])),
    servers(
        (url = "https://api.suvidhaone.gov.in/v1", description = "Production"),
        (url = "https://staging-api.suvidhaone.gov.in/v1", description =
"Staging"),
    )
)]
pub struct ApiDoc;
```

9.2 API Design Standards

STANDARD	RULE	EXAMPLE
Versioning	URL-path versioning: /v1/	/v1/bills/pay, /v2/bills/pay (breaking change)
HTTP Methods	REST semantics enforced strictly	GET=read, POST=create, PUT=replace, PATCH=update, DELETE=remove

Response envelope	All responses wrapped in standard envelope	{"data": {...}, "meta": {"request_id": "...", "ts": "..."}}
Error format	RFC 7807 Problem Details for HTTP APIs	{"error_code": 1003, "message": "...", "request_id": "..."}
Pagination	Cursor-based for large result sets	?cursor=<opaque>&limit=20 — no offset pagination
Field naming	snake_case in JSON (Serde rename_all)	user_id, created_at, mobile_hash
Date format	ISO 8601 UTC strings	"2026-02-01T14:30:00Z"
Empty responses	204 No Content for delete/void actions	DELETE /session → 204 No Content

9.3 Standard Response Wrapper

```
#[derive(Serialize)]
pub struct ApiResponse<T: Serialize> {
    pub data:  T,
    pub meta:  Meta,
}

#[derive(Serialize)]
pub struct Meta {
    pub request_id: Uuid,
    pub timestamp:  DateTime<Utc>,
    pub version:    &'static str,
}

// Convenience constructor used in every handler
pub fn ok<T: Serialize>(data: T) -> (StatusCode, Json<ApiResponse<T>>) {
    (StatusCode::OK, Json(ApiResponse {
        data,
        meta: Meta {
            request_id: Uuid::new_v4(),
            timestamp:  Utc::now(),
            version:    "1.0.0",
        },
    }))
}
```

SECTION 10 — Webhooks: Design & Delivery

10. Webhooks — Design & Delivery

SUVIDHA ONE receives inbound webhooks from payment gateways (NPCI/UPI) and DISCOM APIs, and emits outbound webhooks to department systems (e.g., municipal complaint status updates). All webhook processing is asynchronous and idempotent.

10.1 Inbound Webhook Handler — UPI Payment Callback

```
/// POST /webhooks/upi/callback
/// Called by NPCI when a UPI transaction settles
pub async fn upi_payment_callback(
    headers:      HeaderMap,
    State(state): State<AppState>,
    body:         Bytes,
) -> Result<StatusCode, AppError> {
    // 1. Verify HMAC-SHA256 signature from NPCI
    let signature = headers
        .get("X-NPCI-Signature")
        .and_then(|v| v.to_str().ok())
        .ok_or(AppError::Validation("Missing webhook signature".into()))?;

    verify_npci_signature(&body, signature, &state.npci_webhook_secret)?;

    // 2. Parse payload
    let event: UpiWebhookEvent = serde_json::from_slice(&body)
        .map_err(|e| AppError::Validation(e.to_string()))?;

    // 3. Idempotency check — NPCI may retry on timeout
    let key = format!("webhook:upi:{}", event.transaction_id);
    let mut conn = state.redis.get().await?;
    if conn.set_nx::<_, _, bool>(&key, 1u8).await? == false {
        // Already processed — acknowledge without processing again
        return Ok(StatusCode::OK);
    }
    conn.expire(&key, 86_400i64).await?;

    // 4. Process asynchronously — respond to NPCI immediately
    let state_clone = state.clone();
    tokio::spawn(async move {
        if let Err(e) = process_upi_settlement(&event, &state_clone).await {
            tracing::error!(txn_id = %event.transaction_id, error = %e,
                "Failed to process UPI webhook");
        }
    });

    // 5. Immediately acknowledge — NPCI requires < 5s response
    Ok(StatusCode::OK)
}
```

10.2 Outbound Webhook Delivery with Retry

```
pub struct WebhookDeliveryService {
    http:         reqwest::Client,
    webhook_repo: Arc<dyn WebhookRepository>,
}

impl WebhookDeliveryService {
    pub async fn deliver(&self, webhook: &OutboundWebhook) -> Result<(),
AppError> {
        let max_attempts = 5;
        let mut attempt  = 0;

        loop {
            attempt += 1;
            match self.try_deliver(webhook).await {
                Ok(_) => {
                    self.webhook_repo.mark_delivered(webhook.id).await?;
                    return Ok(());
                }
                Err(e) if attempt >= max_attempts => {
                    self.webhook_repo.mark_failed(webhook.id,
&e.to_string()).await?;
                    tracing::error!(webhook_id = %webhook.id, "Webhook delivery
exhausted retries");
                    return Err(e);
                }
                Err(e) => {
                    // Exponential backoff: 1s, 2s, 4s, 8s, 16s
                    let delay = Duration::from_secs(2u64.pow(attempt - 1));
                    tracing::warn!(attempt, delay_secs = delay.as_secs(),
                        "Webhook delivery failed, retrying: {}", e);
                    tokio::time::sleep(delay).await;
                }
            }
        }
    }

    async fn try_deliver(&self, wh: &OutboundWebhook) -> Result<(), AppError> {
        // Sign payload with HMAC for receiver to verify
        let signature = sign_payload(&wh.payload, &wh.secret)?;
        self.http
            .post(&wh.url)
            .header("X-Suvidha-Signature", signature)
            .header("X-Suvidha-Event",     &wh.event_type)
            .json(&wh.payload)
            .timeout(Duration::from_secs(10))
            .send()
            .await
            .map_err(|e| AppError::ExternalApi(e.to_string()))?;
        Ok(())
    }
}
```

SECTION 11 — Logging, Monitoring & Observability

11. Logging, Monitoring & Observability

11.1 Structured Logging with tracing

```
// main.rs — tracing setup
use tracing_subscriber::{layer::SubscriberExt, util::SubscriberInitExt,
EnvFilter};

pub fn init_tracing() {
    tracing_subscriber::registry()
        .with(EnvFilter::from_default_env())   // RUST_LOG=info,sqlx=warn
        .with(tracing_subscriber::fmt::layer()
            .json()                             // Structured JSON logs for ELK
            .with_current_span(true)
            .with_span_events(tracing_subscriber::fmt::format::FmtSpan::CLOSE)
        )
        .init();
}

// Example instrumented handler
#[tracing::instrument(skip(state), fields(user_id = %claims.sub))]
pub async fn pay_bills(
    Extension(claims): Extension<AccessClaims>,
    State(state):       State<AppState>,
    Validated(req):     Validated<PayBillRequest>,
) -> Result<impl IntoResponse, AppError> {
    tracing::info!(bill_count = req.bill_ids.len(), method = ?req.method,
"Payment initiated");

    let receipt = state.payment_svc
        .pay_bills(claims.sub, &req.bill_ids, req.method, req.idempotency_key)
        .await?;

    tracing::info!(txn_id = %receipt.transaction_id, amount = %receipt.total,
"Payment successful");
    Ok(ok(receipt))
}
```

11.2 Prometheus Metrics

```
use prometheus::{Counter, Histogram, IntGauge, Registry, histogram_opts, opts};

#[derive(Clone)]
pub struct Metrics {
    pub requests_total:     Counter,
    pub request_duration:   Histogram,
    pub payment_success:    Counter,
    pub payment_failure:    Counter,
    pub active_sessions:    IntGauge,
    pub db_pool_size:       IntGauge,
}
```

```
impl Metrics {
    pub fn new(registry: &Registry) -> Self {
        let request_duration = Histogram::with_opts(
            histogram_opts!("http_request_duration_seconds", "HTTP request
latency",
                vec![0.005, 0.01, 0.025, 0.05, 0.1, 0.25, 0.5, 1.0, 2.5, 5.0]
            )
        ).unwrap();
        registry.register(Box::new(request_duration.clone())).unwrap();
        // ... register other metrics
        Self { request_duration, /* ... */ }
    }
}
```

11.3 Key Metrics & Alert Thresholds

METRIC	TYPE	TARGET / THRESHOLD	ALERT CONDITION
http_request_duration_seconds (p95)	Histogram	< 200ms target / 500ms SLA	p95 > 2s for 10 min → Medium
payment_success_rate	Gauge	> 99.5%	> 10% failures → High
auth_success_rate	Gauge	> 98%	> 5% failures for 5 min → High
error_rate	Counter	< 0.1%	> 5% for 5 min → Critical
db_pool_connections	IntGauge	< 80% of max_size	> 80% of max → Critical
active_sessions	IntGauge	Informational	Sudden drop → High (possible outage)
kiosk_heartbeat_missing	Counter	0 missing kiosks	> 20 kiosks offline → High

11.4 Distributed Tracing (OpenTelemetry)

```
// Trace context is propagated across all microservices
// via W3C traceparent headers

use opentelemetry::global;
use tracing_opentelemetry::OpenTelemetryLayer;

pub fn init_tracing_with_otlp(service_name: &str) {
    let tracer = opentelemetry_otlp::new_pipeline()
        .tracing()
        .with_exporter(
            opentelemetry_otlp::new_exporter()
                .tonic()
                .with_endpoint("http://otel-collector:4317")
        )
        .install_batch(opentelemetry_sdk::runtime::Tokio)
        .unwrap();

    tracing_subscriber::registry()
        .with(OpenTelemetryLayer::new(tracer))
```

```
            .with(tracing_subscriber::fmt::layer().json())
            .init();
    }
```

SECTION 12 — Testing & Code Quality

12. Testing & Code Quality

12.1 Testing Strategy

TEST TYPE	TOOL / CRATE	SCOPE	COVERAGE TARGET
Unit tests	Built-in Rust #[test]	BLL functions, parsers, validators	≥ 90% of BLL code
Integration tests	sqlx + testcontainers-rs	Repository + real PostgreSQL/Redis	All CRUD paths
API (e2e) tests	axum::test + reqwest	Full request → response including middleware	All routes
Load tests	k6.io	1M req/min simulation	p99 < 500ms at peak
Security tests	cargo-audit + OWASP ZAP	Dependency CVEs + endpoint fuzzing	CI gate — 0 criticals
Property tests	proptest	Serialization round-trips, edge inputs	Key data models

12.2 Unit Test Example — OTP Service

```
#[cfg(test)]
mod tests {
    use super::*;
    use mockall::predicate::*;
    use mockall::mock;

    mock! {
        RedisConn {}
        #[async_trait]
        impl RedisCache for RedisConn {
            async fn get(&mut self, key: &str) -> Result<Option<String>,
CacheError>;
            async fn set_ex(&mut self, key: &str, val: &str, ttl: usize) ->
Result<(), CacheError>;
            async fn del(&mut self, key: &str) -> Result<(), CacheError>;
        }
    }

    #[tokio::test]
    async fn test_otp_expired_returns_error() {
        let mut mock_redis = MockRedisConn::new();
        // Simulate no OTP in cache (expired)
        mock_redis.expect_get()
            .with(eq("otp:hash:9999900000"))
            .returning(|_| Ok(None));
```

```
        let result = verify_otp("9999900000", "123456", &mut mock_redis).await;

        assert!(matches!(result, Err(AppError::Auth(AuthError::OtpExpired))));
    }

    #[tokio::test]
    async fn test_otp_wrong_code_increments_attempt() {
        let mut mock_redis = MockRedisConn::new();
        // Return mismatched hash
        mock_redis.expect_get()
            .returning(|_| Ok(Some("deadbeef".into())));
        mock_redis.expect_get()  // attempt counter
            .returning(|_| Ok(Some("0".into())));
        mock_redis.expect_incr().returning(|_, _| Ok(1u8));

        let result = verify_otp("9999900000", "111111", &mut mock_redis).await;
        assert!(matches!(result, Err(AppError::Auth(AuthError::InvalidOtp))));
    }
}
```

12.3 Integration Test Example — Bill Payment

```
#[sqlx::test(fixtures("users", "bills"))]
async fn test_pay_bill_success(pool: PgPool) {
    let redis = create_test_redis().await;
    let state = build_test_app_state(pool, redis);
    let app   = build_router(state);

    // Arrange: authenticated request
    let token = issue_test_jwt(TEST_USER_ID);
    let response = app
        .oneshot(
            Request::builder()
                .method("POST")
                .uri("/api/v1/bills/pay")
                .header("Authorization", format!("Bearer {}", token))
                .header("Content-Type", "application/json")
                .body(Body::from(serde_json::to_string(&json!({
                    "bill_ids": [TEST_BILL_ID],
                    "method":   "Upi",
                    "idempotency_key": Uuid::new_v4(),
                })).unwrap()))
                .unwrap(),
        )
        .await
        .unwrap();

    assert_eq!(response.status(), StatusCode::OK);
    let body: serde_json::Value = parse_body(response).await;
    assert!(body["data"]["transaction_id"].is_string());
}
```

12.4 Code Quality Gates (CI Pipeline)

```
# .github/workflows/ci.yml
- name: Format check
  run: cargo fmt -- --check
```

```
  - name: Clippy (deny warnings)
    run: cargo clippy --all-targets -- -D warnings

  - name: Unit tests
    run: cargo test --lib

  - name: Integration tests
    run: cargo test --test '*'

  - name: Audit dependencies for CVEs
    run: cargo audit --deny warnings

  - name: Code coverage (minimum 80%)
    run: cargo tarpaulin --out Xml --fail-under 80
```

SECTION 13 — Configuration Management

13. Configuration Management

> *Never commit secrets to source control. All sensitive values (JWT keys, API credentials, DB passwords) are injected at runtime via Kubernetes Secrets or environment variables.*

13.1 Typed Configuration with config-rs

```
use config::{Config, Environment};
use serde::Deserialize;

#[derive(Debug, Deserialize, Clone)]
pub struct AppConfig {
    pub server:    ServerConfig,
    pub database:  DatabaseConfig,
    pub redis:     RedisConfig,
    pub jwt:       JwtConfig,
    pub uidai:     UidaiConfig,
    pub npci:      NpciConfig,
    pub sms:       SmsConfig,
}

#[derive(Debug, Deserialize, Clone)]
pub struct JwtConfig {
    pub private_key_pem: String,  // Mounted from K8s Secret
    pub public_key_pem:  String,
    pub access_ttl_secs: u64,     // default 900
    pub refresh_ttl_secs: u64,    // default 604800
}

pub fn load_config() -> Result<AppConfig, config::ConfigError> {
    Config::builder()
        // Base defaults
        .add_source(config::File::with_name("config/default"))
        // Environment-specific overrides
        .add_source(config::File::with_name(
            &format!("config/{}", std::env::var("APP_ENV").unwrap_or_default())
        ).required(false))
        // Environment variables override all (DATABASE_URL, REDIS_URL, etc.)
        .add_source(Environment::with_prefix("SUVIDHA").separator("__"))
        .build()?
        .try_deserialize()
}
```

13.2 Environment Variables Reference

VARIABLE	SERVICE	EXAMPLE VALUE	SECRET?
DATABASE_URL	All	postgresql://user:pass@db/suvidha	Yes

REDIS_URL	All	redis://redis:6379	Yes
JWT_PRIVATE_KEY_PEM	auth	<RSA-2048 PEM>	Yes
JWT_PUBLIC_KEY_PEM	All	<RSA-2048 PEM public>	No
OTP_HMAC_SECRET	auth	<32-byte random hex>	Yes
UIDAI_API_KEY	auth	<UIDAI AUA key>	Yes
NPCI_MERCHANT_ID	payment	<BBPS merchant ID>	Yes
NPCI_WEBHOOK_SECRET	payment	<HMAC webhook secret>	Yes
DIGILOCKER_CLIENT_ID	document	<DigiLocker OAuth client>	Yes
SMS_PROVIDER_API_KEY	notification	<Airtel/Jio API key>	Yes
RUST_LOG	All	info,sqlx=warn,tower=info	No
APP_ENV	All	production | staging | dev	No

SECTION 14 — Database Interactions & CRUD Operations

14. Database Interactions & CRUD Operations

SUVIDHA ONE uses SQLx with compile-time verified queries — invalid SQL or type mismatches are caught at compile time, not in production. All database access goes through the repository pattern described in Section 6.

14.1 Connection Pool Setup

```
use sqlx::postgres::{PgPool, PgPoolOptions};

pub async fn create_pg_pool(database_url: &str) -> Result<PgPool, sqlx::Error>
{
    PgPoolOptions::new()
        .max_connections(50)          // ~50 per service pod
        .min_connections(5)           // Keep warm connections
        .acquire_timeout(Duration::from_secs(5))
        .idle_timeout(Duration::from_secs(60))
        .max_lifetime(Duration::from_secs(1800))
        .connect(database_url)
        .await
}
```

14.2 Create — INSERT with RETURNING

```
#[derive(Debug, Serialize, Deserialize, sqlx::FromRow)]
pub struct User {
    pub user_id:     Uuid,
    pub full_name:   String,
    pub state_code:  String,
    pub preferred_language: String,
    pub created_at:  DateTime<Utc>,
}

pub async fn create_user(pool: &PgPool, req: &CreateUserRequest) ->
Result<User, sqlx::Error> {
    sqlx::query_as!(User,
        r#"
        INSERT INTO users (user_id, aadhaar_id_hash, mobile_hash, full_name,
state_code, preferred_language)
        VALUES ($1, $2, $3, $4, $5, $6)
        ON CONFLICT (aadhaar_id_hash) DO UPDATE
            SET full_name = EXCLUDED.full_name,
                updated_at = NOW()
        RETURNING user_id, full_name, state_code, preferred_language,
created_at
        "#,
        Uuid::new_v4(),
        req.aadhaar_id_hash,
        req.mobile_hash,
        req.full_name,
        req.state_code,
        req.preferred_language,
    )
```

```
    .fetch_one(pool)
    .await
}
```

14.3 Read — Fetch Single & List with Cursor Pagination

```
// Fetch single user by ID
pub async fn get_user_by_id(pool: &PgPool, id: Uuid) -> Result<Option<User>,
sqlx::Error> {
    sqlx::query_as!(User,
        "SELECT user_id, full_name, state_code, preferred_language, created_at
         FROM users WHERE user_id = $1 AND is_active = true",
        id
    )
    .fetch_optional(pool)
    .await
}

// Cursor-based pagination — no OFFSET (doesn't scale)
pub async fn list_transactions(
    pool:   &PgPool,
    user_id: Uuid,
    cursor:  Option<DateTime<Utc>>,   // created_at of last item seen
    limit:   i64,
) -> Result<Vec<Transaction>, sqlx::Error> {
    sqlx::query_as!(Transaction,
        r#"
        SELECT * FROM transactions
        WHERE user_id = $1
          AND ($2::timestamptz IS NULL OR created_at < $2)
        ORDER BY created_at DESC
        LIMIT $3
        "#,
        user_id,
        cursor,
        limit,
    )
    .fetch_all(pool)
    .await
}
```

14.4 Update — PATCH with Partial Fields

```
pub async fn update_preferences(
    pool:    &PgPool,
    user_id: Uuid,
    prefs:   &UpdatePreferences,
) -> Result<(), sqlx::Error> {
    sqlx::query!(
        "UPDATE users
         SET preferred_language     = COALESCE($2, preferred_language),
             accessibility_settings = COALESCE($3, accessibility_settings),
             updated_at             = NOW()
         WHERE user_id = $1",
        user_id,
        prefs.preferred_language,
        prefs.accessibility_settings.as_ref().map(|s|
serde_json::to_value(s).unwrap()),
    )
    .execute(pool)
```

```
    .await?;
    Ok(())
}
```

14.5 Delete — Soft Delete Pattern

```
// SUVIDHA ONE never hard-deletes citizen records (audit + DPDP compliance)
// Soft delete: set is_active = false
pub async fn deactivate_user(pool: &PgPool, user_id: Uuid) -> Result<(),
sqlx::Error> {
    sqlx::query!(
        "UPDATE users SET is_active = false, updated_at = NOW() WHERE user_id =
$1",
        user_id
    )
    .execute(pool)
    .await?;
    Ok(())
}
```

14.6 Transactions — Atomic Bill Payment

```
/// Pay multiple bills atomically. If any step fails, the entire operation
rolls back.
pub async fn atomic_bill_payment(
    pool:    &PgPool,
    user_id: Uuid,
    bill_ids: &[Uuid],
    tx_ref:  &str,
    total:   Decimal,
) -> Result<PaymentRecord, sqlx::Error> {
    // Begin explicit transaction
    let mut tx = pool.begin().await?;

    // 1. Mark bills as paid within the transaction
    for bill_id in bill_ids {
        sqlx::query!(
            "UPDATE bills SET status = 'Paid', paid_at = NOW() WHERE bill_id =
$1",
            bill_id
        )
        .execute(&mut *tx)
        .await?;
    }

    // 2. Create payment record within same transaction
    let payment = sqlx::query_as!(PaymentRecord,
        "INSERT INTO payments (payment_id, user_id, amount, tx_ref, status)
         VALUES ($1, $2, $3, $4, 'Success')
         RETURNING *",
        Uuid::new_v4(), user_id, total, tx_ref
    )
    .fetch_one(&mut *tx)
    .await?;

    // 3. Commit — both bill updates and payment record committed together
    tx.commit().await?;
    Ok(payment)
}
```

SECTION 15 — Serialization & Deserialization (Serde)

15. Serialization & Deserialization (Serde)

Serde is Rust's zero-cost serialization framework. SUVIDHA ONE uses Serde for JSON (API bodies), binary (internal gRPC), and database JSONB field deserialization. Serde transformations happen at compile time — there is no runtime reflection overhead.

15.1 Core Serde Patterns

```
use serde::{Deserialize, Serialize};
use serde_with::{serde_as, DisplayFromStr};

#[serde_as]
#[derive(Debug, Serialize, Deserialize, Clone, PartialEq)]
#[serde(rename_all = "camelCase")]  // JSON uses camelCase; Rust uses
snake_case
pub struct BillDetails {
    pub bill_id:       Uuid,
    pub consumer_id:   String,

    #[serde_as(as = "DisplayFromStr")]
    pub amount:        Decimal,        // Precise decimal, not float

    pub due_date:      NaiveDate,       // Serde: "2026-03-15"
    pub department:    Department,      // Enum → string in JSON
    pub status:        BillStatus,

    #[serde(skip_serializing_if = "Option::is_none")]
    pub description:   Option<String>,  // Omitted if null

    #[serde(skip)]
    pub internal_ref:  String,          // Never exposed in API responses
}

#[derive(Debug, Serialize, Deserialize, Clone, PartialEq)]
#[serde(rename_all = "SCREAMING_SNAKE_CASE")]
pub enum Department {
    Electricity,  // JSON: "ELECTRICITY"
    Water,
    Gas,
    Municipal,
}
```

15.2 Custom Deserializer — Sanitized Mobile Number

```
use serde::{de, Deserializer};
use std::fmt;

/// Custom deserializer: strips non-digits, validates 10-digit Indian mobile
pub fn deserialize_mobile<'de, D>(deserializer: D) -> Result<String, D::Error>
where
    D: Deserializer<'de>,
```

```
{
    struct MobileVisitor;

    impl<'de> de::Visitor<'de> for MobileVisitor {
        type Value = String;

        fn expecting(&self, f: &mut fmt::Formatter) -> fmt::Result {
            write!(f, "a 10-digit Indian mobile number")
        }

        fn visit_str<E: de::Error>(self, v: &str) -> Result<String, E> {
            let digits: String = v.chars().filter(|c|
c.is_ascii_digit()).collect();
            let normalized = digits.trim_start_matches("91");  // Strip country
code
            if normalized.len() != 10 {
                return Err(E::custom(format!("Invalid mobile number: {}", v)));
            }
            Ok(normalized.to_string())
        }
    }

    deserializer.deserialize_str(MobileVisitor)
}

#[derive(Deserialize)]
pub struct SendOtpRequest {
    #[serde(deserialize_with = "deserialize_mobile")]
    pub mobile: String,
}
```

15.3 JSONB Deserialization from PostgreSQL

```
/// Accessibility settings stored as JSONB in PostgreSQL
#[derive(Debug, Serialize, Deserialize, Clone, sqlx::Type)]
#[sqlx(type_name = "jsonb")]
pub struct AccessibilitySettings {
    #[serde(default)]
    pub font_scale:    f32,          // 1.0 | 1.3 | 1.5
    #[serde(default)]
    pub high_contrast: bool,
    #[serde(default = "default_true")]
    pub voice_enabled: bool,
}

fn default_true() -> bool { true }

// Reading JSONB from DB via sqlx requires implementing
From<sqlx::types::JsonValue>
impl sqlx::decode::Decode<'_, sqlx::Postgres> for AccessibilitySettings {
    fn decode(value: sqlx::postgres::PgValueRef) -> Result<Self, Box<dyn
std::error::Error + Send + Sync>> {
        let json: serde_json::Value = sqlx::decode::Decode::decode(value)?;
        Ok(serde_json::from_value(json)?)
    }
}
```

15.4 Performance: Zero-Copy Deserialization

```rust
/// For large payloads, borrow from input buffer instead of cloning
#[derive(Debug, Deserialize)]
pub struct WebhookPayload<'a> {
    pub event_type:     &'a str,      // Borrowed — zero copy from input
    pub transaction_id: &'a str,
    pub data:           &'a serde_json::value::RawValue,  // Defer parsing
}

pub fn parse_webhook(body: &[u8]) -> Result<WebhookPayload<'_>,
serde_json::Error> {
    serde_json::from_slice(body)  // Borrows directly from body buffer
}
```

SECTION 16 — Appendix: Dependencies, Ports & Quick Reference

16. Appendix

16.1 Full Dependency List (Cargo.toml)

CRATE	VERSION	PURPOSE
axum	0.7	Async web framework (Tokio-native, Tower-compatible)
tokio	1.*	Async runtime (full features: rt, net, time, sync)
tower	0.4	Middleware trait (rate-limit, auth layers)
tower-http	0.5	HTTP-specific middleware (CORS, compression, headers)
serde	1.*	Serialization framework (with derive feature)
serde_json	1.*	JSON serialize/deserialize
serde_with	3.*	Extended serde helpers (DisplayFromStr, etc.)
sqlx	0.7	Async, compile-time verified PostgreSQL driver
deadpool-redis	0.12	Async Redis connection pool
jsonwebtoken	9.*	JWT encode/decode (RS256, HS256)
validator	0.16	Struct-level input validation with derive macro
thiserror	1.*	Ergonomic error enum derivation
anyhow	1.*	Flexible error handling for application code
tracing	0.1	Structured, async-aware logging framework
tracing-subscriber	0.3	Tracing output layer (JSON, stdout)
opentelemetry	0.21	Distributed tracing (OTLP export to Jaeger)
prometheus	0.13	Metrics collection and Prometheus exposition
reqwest	0.11	Async HTTP client (UIDAI, NPCI, DigiLocker calls)
uuid	1.*	UUID v4 generation with Serde support
chrono	0.4	Date/time types with Serde and SQLx support

rust_decimal	1.* | Exact decimal arithmetic for financial amounts
hmac	0.12 | HMAC-SHA256 for OTP and webhook signature
sha2	0.10 | SHA-256 hash primitive
rand	0.8 | Cryptographically secure random number generation
hex	0.4 | Hex encoding/decoding for hashes
constant_time_eq	0.3 | Constant-time comparison (prevents timing attacks)
utoipa	4.* | OpenAPI 3.1 spec generation from code annotations
config	0.13 | Layered configuration management
dotenvy	0.15 | .env file loading in development

16.2 Service Ports Quick Reference

SERVICE / COMPONENT	PORT
API Gateway (NGINX)	80 (HTTP) / 443 (HTTPS)
auth-service	3001
payment-service	3002
utility-service	3003
grievance-service	3004
document-service	3005
notification-service	3006
session-service	3007
kiosk-service	3008
PostgreSQL	5432
Redis	6379
MinIO (S3)	9000 (API) / 9001 (Console)
Prometheus	9090
Grafana	3000
Jaeger (tracing UI)	16686

OTEL Collector	4317 (gRPC) / 4318 (HTTP)

16.3 Production Checklist

- ✅JWT uses RS256 with 2048-bit RSA keys — private key never leaves auth-service
- ✅All API endpoints are rate-limited — auth at 5 req/min, global at 1000 req/min per IP
- ✅OTP stored as HMAC-SHA256 hash, never in plaintext
- ✅Aadhaar VID tokenization — raw Aadhaar number never stored or logged
- ✅All payments offloaded to PCI-DSS Level 1 gateway — no card data on our infrastructure
- ✅Immutable audit log — write-once PostgreSQL partition + forwarded to ELK SIEM
- ✅DPDP Act 2023 compliance — consent screen, data minimization, right-to-erasure API
- ✅Cargo audit gates in CI — zero known critical CVEs in production build
- ✅Health check endpoints on all services — Kubernetes liveness + readiness probes
- ✅Distributed tracing across all 8 services via W3C traceparent propagation
- ✅sqlx compile-time query verification — SQL injection impossible via type system
- ✅Offline mode for kiosk — IndexedDB cache + background sync API

SUVIDHA ONE — Rust Backend Documentation

Team: The_Dark_Knight | ID: 21 | Version 1.0 | February 2026

Built for 1,000,000+ Users Per Minute • Safety • Throughput • Auditability
